Homomorphisms

- A **homomorphism** on an alphabet is a function that gives a string for each symbol in that alphabet.
- **Example:** $h(0) = ab$, $h(1) = \varepsilon$.
- Extend to strings by $h(a_1a_2 \dots a_n) = h(a_1)h(a_2) \dots h(a_n)$.
- **Example:** $h(01010) = ababab$.

Closure Properties: Homomorphism

- If L is regular, and h is a homomorphism on its alphabet, then $h(L) = \{h(w) \mid w \in L\}$ is also regular.
- **Proof:** Let E be a regular expression for L .
- Apply h to each symbol in E .
- Language of resulting RE is $h(L)$.

Closure under Homomorphism: Example

- Let $h(0) = ab$, $h(1) = \varepsilon$.
- Let L be the language of a regular expression $01^* + 10^*$.
- Then $h(L)$ is the language of regular expression $ab\varepsilon^* + \varepsilon(ab)^*$.
- **Note:** $ab\varepsilon^* + \varepsilon(ab)^* = ab + (ab)^* = (ab)^*$.

Inverse Homomorphisms

- Let h be a homomorphism and L a language whose alphabet is the output language of h .
- $h^{-1}(L) = \{w \mid h(w) \in L\}$.

Inverse Homomorphisms: Example

- Let $h(0) = ab$, $h(1) = \varepsilon$.
- Let $L = \{abab, baba\}$.
- $h^{-1}(L) =$ the language with two 0's and any number of 1's = $L(1^*01^*01^*)$.
- **Note:** No string maps to $baba$, any string with exactly two 0's maps to $abab$.

Closure Proof for Inverse Homomorphism

- Start with a DFA A for L .
- Construct a DFA B for $h^{-1}(L)$ with:
 - The **same** set of states.
 - The **same** start state.
 - The **same** final states.
 - Input alphabet = the symbols to which the homomorphism h applies.
- The **transitions** for B are computed by applying h to an input symbol a and seeing where A would go on sequence of input symbols $h(a)$.
- Formally, $\delta_B(q,a) = \delta_A(q,h(a))$.

Inverse Homomorphism Construction: Example

- $h(0) = ab, h(1) = \varepsilon$.

Closure Proof for Inverse Homomorphism

- **Induction** on $|w|$ shows that $\delta_B(q_0, w) = \delta_A(q_0, h(w))$.
- **Basis:** $w = \varepsilon$.
 $\delta_B(q_0, \varepsilon) = q_0$, and
 $\delta_A(q_0, h(\varepsilon)) = \delta_A(q_0, \varepsilon) = q_0$.
- **Inductive Step:** Let $w = xa$, assume **IH** for x .
- $\delta_B(q_0, w) = \delta_B(\delta_B(q_0, x), a) = \delta_B(\delta_A(q_0, h(x)), a)$ (from **IH**)
- $= \delta_A(\delta_A(q_0, h(x)), h(a))$ (by definition of **B**)
- $= \delta_A(q_0, h(x)h(a))$ (by definition of extended δ_A)
- $= \delta_A(q_0, h(w))$ (by definition of **h**)

Decision Property: Equivalence

- Given regular languages L and M , is $L = M$?
- Algorithm involves constructing the product DFA P from DFA's for L and M .
- Make the final states of P be those states $[q,r]$ such that exactly one of q and r is a final state of its own DFA.
- Thus, P accepts w iff w is in exactly one of L and M .
- The product DFA's language is empty iff $L = M$.
- **Note:** We already have a better algorithm to test emptiness.

Minimum State DFA

- In principle, since we can test for equivalence of DFA's we can, given a DFA A find the DFA with the fewest states accepting $L(A)$.
- Test **all** smaller DFA's for equivalence with A .
- But that's a **terrible** algorithm.

Efficient State Minimization

- Construct a table with **all pairs** of states.
- If you find a string that **distinguishes** two states (takes **exactly** one to an accepting state), mark that pair.
- Algorithm is a **recursion** on the length of the **shortest** distinguishing string.

Efficient State Minimization

- **Basis:** Mark a pair if exactly one is a final state.
- **Induction:** Mark $[q,r]$ if there is some input symbol a such that $[\delta(q,a),\delta(r,a)]$ is marked.
- After no more marks are possible, the **unmarked** states are equivalent and can be merged into one state.

Constructing the Minimum State DFA

- Suppose q_1, \dots, q_k are indistinguishable states.
- Replace them by one state q .
- Then $\delta(q_1, a), \dots, \delta(q_k, a)$ are all indistinguishable states, otherwise, we should have marked at least one more pair.
- Let $\delta(q, a) =$ the representative state for that group.

Eliminating Indistinguishable States

- Unfortunately, combining indistinguishable states could leave us with **unreachable** states in the **minimum-state** DFA.
- Thus, before or after, **remove** states that are not reachable from the start state.

Example: State Minimization

Transitivity of “Indistinguishable”

Proposition

If state p is indistinguishable from q , and q is indistinguishable from r , then p is indistinguishable from r .

- **Proof:** The outcome (accept or don't) of p and q on input w is the same, and the outcome of q and r on w is the same, then likewise the outcome of p and r .

- We have combined states of the given DFA **whenever** possible.
- Could there be another, completely unrelated DFA with **fewer** states?
- **No**. The proof involves **minimizing** the DFA we derived with the **hypothetical** better DFA.

Proof: No Unrelated, Smaller DFA

- Let **A** be our minimized DFA; let **B** be a smaller equivalent.
- Consider an automaton with the states of **A** and **B** combined.
- Use **distinguishable** in its **contrapositive** form:
 - If states **q** and **p** are indistinguishable, so are $\delta(\mathbf{q},\mathbf{a})$ and $\delta(\mathbf{p},\mathbf{a})$.

Hypothesis

Every state q of A is indistinguishable from some state of B .

- Induction is on the length of the shortest string taking you from the start state of A to q .

- **Basis:** Start states of **A** and **B** are **indistinguishable**, because $L(A) = L(B)$.
- **Induction:** Suppose $w = xa$ is a **shortest** string getting **A** to state **q**.
- By the **IH**, **x** gets **A** to some state **r** that is indistinguishable from some state **p** of **B**.
- Then $\delta(r,a) = q$ is indistinguishable from $\delta(p,a)$.

- **Key idea:** Two states of **A** cannot be indistinguishable from the same state of **B**, or they would be indistinguishable from each other.
 - But **A** is already a minimum state DFA!
- Thus, **B** has at least as many states as **A**.

Fibonacci Numbers and the Golden Ratio

$$F_n = F_{n-1} + F_{n-2}$$
$$\Rightarrow F_n = \frac{1}{\sqrt{5}} \left\{ \left(\frac{1 + \sqrt{5}}{2} \right)^n - \left(\frac{1 - \sqrt{5}}{2} \right)^n \right\}$$
